The concept of **rational agents**: Central to our approach to AI

- Now, we make this notion more concrete

The concept of rationality can be applied to a variety of agents

- Operations in any imaginable environment

We use this concept to develop a set of successful design principles

↪ Systems that can reasonably be called intelligent

# Intelligent agents (cont.)

The starting observation is that some agents behave better than others

- This leads to the idea of a rational agent
- ↪ One that behaves as well as possible

How well an agent can behave depends on the **environment**

- As, some environments are more difficult than others

We start by giving a crude categorisation of the environments

- We show how their properties influence the agent design

We shall also describe a number of basic ‘skeleton’ agent designs

# Agents and environment

## Definition

An *agent* is anything viewed as

- 1 *perceiving* its environment thru *sensors*
- 2 *acting* upon that environment through *actuators*

## Example

### Human agent

- Eyes, ears, and other organs for **sensors**
- Hands, legs, vocal tract, and so on for **actuators**

### Robotic agent

- Cameras and infrared range finders for **sensors**
- Various motors for **actuators**

### Software agent

- Keystrokes, file contents, incoming net packets as **sensory inputs**
- Displaying, writing files, outgoing net packets, as **acting outputs**

We use the term **percept** to refer to the agent's perceptual inputs

↪ at any given instant

A **percept sequence** is the history of everything ever perceived

## Remark

In general, an agent's choice of action at any given instant can depend on the entire percept sequence observed to date

- But it can NOT depend on anything it has NOT perceived

The specification of the agent's choice of action, for ALL possible percept sequences, says everything about the agent

Imagine tabulating the agent function that describes any agent

- For most agents, this would be a very large table

Table is infinite, unless length of percept sequences is bounded

Given an agent to experiment with, we could construct this table

- ↪ Try out all possible percept sequences
- ↪ Record which actions the agent does in response

The table is an external characterisation of the agent

## Definition

*Internally, the agent function will be implemented by an **agent program***

| :   | :            |

Various agents can be defined by filling the ‘action’ column in various ways

- What is the right way to fill out the table?

We are asking what makes an agent good/bad, intelligent/dumb?

## Remark

The notion of agent is meant to be a tool for analysing systems

- The world is not divided into agents and non-agents
- It is not an absolute characterisation

## Example

One can view a hand-held calculator as an agent

- The agent chooses the action of displaying '4'
- Given the percept sequence '2+2='

A **rational agent** is defined as one that **does the right thing**

- Every entry in the table is filled out correctly (agent function)

Doing the right thing is better than doing the wrong thing (uh?)

↪ What does it mean to do the right thing?

Age-old question to be answered in an age-old way

↪ We consider the consequences of the agent's behaviour

An agent in an environment generates a sequence of actions

- The actions depend on the percepts it receives

Sequence of actions  $\implies$  Environment through a sequence of its states

$\rightsquigarrow$  If the sequence is *desirable*, the agent performed well

This notion of desirability is captured by a **performance measure**

- It evaluates any given sequence of environment states

Various fixed performance measure for different tasks and agents

- The designer devise one appropriate to the circumstances
- This is not as easy as it sounds

## Remark

*‘As a general rule, it is better to design performance measures according to what one actually wants in the environment, rather than according to how one thinks the agent should behave’*

## Example

Consider the vacuum-cleaner agent

We measure performance by the amount of dirt cleaned up in a 8-hour shift

- With a rational agent, what you ask for is what you get
- It executes actions to maximise the performance measure

The agent could maximise this performance measure

- ① Cleaning up the dirt
- ② Dumping it all on the floor
- ③ Cleaning it up again
- ④ And, so on

Even when obvious pitfalls are avoided, there remain some issues

- The notion of ‘clean floor’ is based on average cleanliness over time

The same average cleanliness can be achieved by different agents

- One agent does a mediocre job, but it functions all the time
- Another agent cleans energetically, but takes long breaks

What is rational at any given time depends on four things

- 1 The performance measure that defines the criterion of success
- 2 The agent's prior knowledge of the environment
- 3 The actions the agent can perform
- 4 The agent's percept sequence to date

This leads to the definition of a rational agent

## Definition

### *Rational agent*

*'For each possible percept sequence, a rational agent should select an action that is expected to maximise its performance measure, given the evidence by the percept sequence and whatever built-in knowledge the agent has'*

## Rationality (cont.)

Let us assume the following

### Assumption

- The performance measure awards ‘one point, for each clean square, at each time step, over a ‘lifetime’ of 1K time steps’
- The ‘geography’ of the environment is known *a priori*
- Dirt distribution and initial location of the agent are unknown *a priori*
  
- The only available actions are **Left**, **Right**, and **Suck**
- The **Left** and **Right** actions move the agent left and right
- When this would take the agent outside the environment, the agent remains where it is
- **Sucking** cleans the current square
- Clean squares stay clean
  
- The agent correctly perceives its location
- The agent perceives whether its location contains dirt

This is trivially true when there is no dirt (00)

Dirt in the initial location and none in the other location (10)

- The world is clean after one step (no agent can do better)

No dirt in the initial location and dirt in the other location (01)

- The world is clean after two steps (no agent can do better)

Dirt in both locations (11)

- The world is clean after three steps (no agent can do better)

The same agent would be irrational, under different circumstances

For example,

- Once all dirt is cleaned up, the agent will oscillate back and forth
- Bad, if the performance measure penalises movements

A better agent for this case would done that does nothing

- Once it is sure that all the squares are clean

If clean squares can become dirty again, the agent should check

↪ Re-clean them if needed, occasionally

The agent will need to explore the environment

- Rather than stick to squares A and B

If the geography of the environment is unknown

Happy hackin

We carefully distinguish between rationality and **omniscience**

- An omniscient agent knows the actual outcome of its actions
- ↪ It can act accordingly

Omniscience is impossible in reality

## Example

I am walking around and I see an old friend across the street

There is no traffic nearby and I am not otherwise engaged

- So, being rational, I start to cross the street

Meanwhile, at 33K feet, a door falls off a passing airliner

- Before I make it to the other side I am flattened

Was I irrational to cross the street?

# Omniscience, learning and autonomy (cont.)

Happy hackin

The example shows that rationality is not the same as perfection

## Remark

↪ **Rationality maximizes expected performance**

↪ **Perfection maximizes actual performance**

Perfection should not be a requirement for agents

We cannot expect agents to do what turns out to be the best action

- It would be impossible to design agents
- Impossible to fulfil the specification

Ensure that the agent is not allowed to engage in sub-intelligent activities

## Example

A percept sequence will not tell that there is a truck approaching fast

- If an agent does not look both ways before crossing

Does our definition of rationality say that it is now OK to cross? NO!

Not rational to cross the road, given this uninformative percept sequence

↪ The risk of accident from crossing without looking is too big

Rationality suggests the 'looking' action before start crossing the street

↪ Looking helps maximize the expected performance

Doing actions to modify future percepts is an important part of rationality

- It is called **information gathering**

## Example

A second example of information gathering

- The **exploration** that must be undertaken by a vacuum-cleaner
- In an initially unknown environment

Our definition requires a rational agent to gather info

↪ To learn from what it perceives

# Omniscience, learning and autonomy (cont.)

Happy hackin

Extreme case: The environment is completely known a priori

- The agent need not perceive or learn
- It simply acts correctly

Such agents are fragile

## Example

### The dung beetle

Digs its nest and lays its eggs, fetches a ball of dung to plug the entrance

- Suppose the ball of dung is removed from its grasp *en route*
- The beetle continues its task, pantomimes plugging the nest
- ... with the non-existent dung ball

It never notices the ball of dung is missing

## Example

### The sphex wasp

- The female sphex will dig a burrow, go out and sting a caterpillar
- Drag it to the burrow, enter the burrow again to check all is well
- Drag the caterpillar inside, and lay its egg

The caterpillar serves as a food source when the eggs hatch

Suppose the caterpillar is moved away while the sphex is doing the check

- It will revert to the 'first drag' step

It will continue the plan w/o modification, even after dozens interventions

## Definition

*Autonomy* (or, lack thereof)

*The extent that an agent relies on the prior knowledge of its designer*

- *Rather than on its own percepts*

A rational agent should be autonomous, it should learn

↪ To compensate for partial or incorrect prior knowledge

# Omniscience, learning and autonomy (cont.)

Reasonable to provide an agent with initial knowledge and ability to learn

- After sufficient experience of its environment, the behaviour can become effectively *independent of prior knowledge*
- Incorporation of learning allows to design a single rational agent that will succeed in a variety of environments

Equipped with a definition of rationality, we start building rational agents

- First, we discuss **task environments**
- ‘Problems’ to which rational agents are ‘solutions’

We begin by showing how to specify a task environment

- We illustrate the process with a number of examples

We show that task environments come in a variety of flavours

- The flavour affects the design for the agent program

# Specification of task environments

| Agent Type  | Performance Measure                                   | Environment                                  | Actuators   | Sensors   |
|-------------|---|--|---|---|
| Taxi driver | Safe, fast, legal, comfortable trip, maximize profits | Roads, other traffic, pedestrians, customers | Steering, accelerator, brake, signal, horn, display | Cameras, sonar, speedometer, GPS, odometer, accelerometer, engine sensors, keyboard |

**Performance measure** the automated driver should aspire to?

- Getting to the correct destination;
- Minimising fuel consumption and wear and tear;
- Minimising the trip time or cost;
- Minimising violations of traffic laws;
- Minimise disturbances to other drivers;
- Maximising safety and passenger comfort;
- Maximising profits

The range of task environments that might arise in AI is vast

- We identify a few dimensions to categorise task environments

These dimensions determine, largely, the right agent design and applicability of the main families of implementation techniques

- The definitions here are informal

## Definition

*Fully observable v partially observable*

*If an agent's sensors give it access to the complete state of the environment at each point in time, then the task environment is **fully observable***

A task environment is effectively fully observable if sensors detect everything

- That are relevant to the choice of action
- Relevance depends on the performance measure

## Remark

Fully observable environments are convenient

- ↪ No need to maintain any internal state
- ↪ No need to keep track of the world

An environment may be **partially observable**: Noisy/inaccurate sensors

- Also because parts of the state are missing from the sensor data

## Example

- A vacuum agent with only a local dirt sensor cannot tell whether there is dirt in other squares
- An automated taxi cannot see what other drivers are thinking

If the agent has no sensors, then the environment is **unobservable**

- One might think that in such cases the agent's plight is hopeless
- The goals may still be achievable, sometimes with certainty

## Definition

### *Single agent v multi-agent*

*The distinction between single- and multi-agent environments is intuitive*

## Example

An agent solving cross-words by itself is in a single-agent environment

- An agent playing chess is in a two-agent environment

There are some subtle issues to be considered

First, we have described how an entity may be viewed as an agent

- We have not explained which entities must be viewed as agents

Does agent  $A$  (taxi driver) have to treat object  $B$  (vehicle) as an agent?

- Or can it treat it merely as an object?
- (behaving according to the laws of physics)

## Remark

The key distinction/question

Is  $B$ 's behaviour best described as maximising a performance measure, whose value depends on agent  $A$ 's behaviour?

### Example

In chess, opponent entity  $B$  is trying to maximize its performance measure

- By the rules of chess, this minimizes agent  $A$ 's performance measure
- Thus, chess is a competitive **multi-agent environment**

### Example

In the taxi-driving environment, avoiding collisions maximizes the performance measure of all agents

- It is a partially cooperative **multi-agent environment**
- It is also a partially competitive (only one car can occupy a parking space) **multi-agent environment**

The design in multi- and in single-agent environments are different

- Communication often emerges as a rational behaviour in multi-agent environments;
- In some competitive environments, randomised behaviour is rational because it avoids the pitfalls of predictability

## Definition

### *Deterministic v stochastic*

*If the next state of the environment is completely determined by the current state and action executed by the agent, then we say the environment is **deterministic***

- *Otherwise, we say it is **stochastic***

No need to worry about uncertainty in fully observable, deterministic envs<sup>1</sup>

- Partially observable environments could appear to be stochastic

---

<sup>1</sup>In our definitions, we ignore uncertainty that arises purely from the actions of other agents in a multi-agent environment  
A game can be deterministic even though each agent may be unable to predict the actions of the others

Most real situations are seriously complex

- It is not possible to keep track of all the unobserved aspects
- For practical purposes, they must be treated as stochastic

## Example

Taxi driving as we described it is stochastic

- One can never predict the behaviour of traffic (or else) exactly

The vacuum world as we described it is deterministic

- Variations include stochastic elements (randomly appearing dirt)
- (or an unreliable suction mechanism)

‘Stochastic’, in which uncertainty about outcomes quantified by probabilities

Non-deterministic environments

- Actions are characterised by their *possible* outcomes
- No probabilities are attached to them

## Remark

Non-deterministic environment descriptions can be associated with performances that require success, for *all possible* outcomes of agent’s actions

## Definition

### *Episodic v sequential*

In *episodic* environments, agent's experience is divided into atomic episodes

- *In each episode the agent receives a percept*
- *Then performs a single action*

↪ *The next episode does not depend on the actions taken in previous episodes*

In *sequential* environments, a decision could affect all future decisions

# Properties of task environments (cont.)

## Example

Many classification tasks are episodic

An agent that has to spot defective parts on an assembly line

- Each decision based on current part, regardless of previous decisions
- The current decision does not affect whether the next part is faulty

Chess and taxi driving are sequential

- In both cases, short-term actions can have long-term consequences

## Definition

### *Static v dynamic*

*If the environment can change while an agent is deliberating, then the environment is **dynamic** for that agent*

- *Otherwise, it is **static***

Static environments are easy to deal with

- No need to keep looking at the world while deciding on an action
- No need to worry about the passage of time
- Dynamic environments continuously ask what to do
- If no decision yet, that counts as deciding to do nothing

# Properties of task environments (cont.)

If the environment itself does not change with passage of time but agent's performance score does, then the environment is **semi-dynamic**

## Example

- Taxi driving is dynamic: Other cars and the taxi itself keep moving while the driving algorithm ponders over what to do next
- Chess, when played with a clock, is semi-dynamic
- Crossword puzzles are static

## Definition

### *Discrete v continuous*

*The discrete/continuous distinction applies to the state of the environment, to the way time is handled, and to the percepts and actions of the agent*

## Example

Chess has a finite number of distinct states (excluding the clock)

- Chess also has a discrete set of percepts and actions

Taxi driving is a continuous-state and continuous-time problem

- Speed and location of the taxi and of the other vehicles take a range of continuous values, and do so smoothly over time
- Taxi-driving actions are also continuous (steering angles, etc.)
- Input from digital cameras is discrete (strictly speaking), but it is treated as representing continuously varying intensities and locations

## Definition

### *Known v unknown*

*Strictly, this distinction refers not to the environment but to the agent's (or designer's) state of knowledge about the 'laws of physics' of the environment*

- *In a **known** environment, outcomes (or outcome probabilities if the environment is stochastic) for all actions are given*
- *If the environment is **unknown**, the agent will have to learn how it works in order to make good decisions*

The distinction between known/unknown environments is not the same as the one between fully-observable/partially-observable environments

It is possible for a known environment to be partially observable

- In solitaire card games, I know the rules
- Still I am unable to see all the cards

An unknown environment can be fully observable

- In a new video game, the screen may show the entire game state
- Still I do not know what the buttons do until I try them

So far we have talked about agents by describing their behaviour

- The action that is performed after any given sequence of percepts

↪ Now we talk about how the inside works

AI designs **agent programs** that implement the **agent function**

↪ The **mapping from percepts to actions**

## Assumption

We assume that the agent program will operate on some sort of computing device with physical sensors and actuators

- We call this the **architecture**
- **agent** = **architecture** + **program**

The program is chosen appropriate for the architecture

- In general, the architecture makes the percepts from the sensors available to the program
- In general, the architecture feeds the program's actions to the actuators as they are generated

The agent programs that we discuss all have the same skeleton:

- They take the current percept as input from the sensors
- They return an action to the actuators

## Remark

Notice the difference between agent program and agent function

- The **agent program** takes the **current percept** as input
- The **agent function** takes the entire **percept history**

The agent program takes just the current percept as input

- Nothing more is available from the environment

An agent can have actions that depend on the entire percept sequence

- It will have to remember the percepts

## Example

A trivial agent program that keeps track of the percept sequence

- It uses it to index into a table of actions to decide what to do

**function** TABLE-DRIVEN-AGENT(*percept*) **returns** an action

**persistent:** *percepts*, a sequence, initially empty

*table*, a table of actions, indexed by percept sequences, initially fully specified

append *percept* to the end of *percepts*

*action* ← LOOKUP(*percepts*, *table*)

**return** *action*

**TABLE-DRIVEN-AGENT** program is invoked for each new percept

- It returns an action each time
- It retains the complete percept sequence in memory

A table-driven approach to agent construction is doomed to fail

- Let  $\mathcal{P}$  be the set of possible percepts
- Let  $T$  be the agent lifetime (total number of percepts it will receive)
- The lookup table will contain  $\sum_{t=1}^T |\mathcal{P}|^t$  entries

## Example

Consider an automated taxi with visual input from a single cam

- Stuff comes in at the rate of  $\sim 27\text{MBs}^2$
- One hour drive: A lookup table of  $+10^{250,000,000,000}$  entries

A lookup table for chess (a tiny, well-behaved fragment of world)

- At least  $10^{150}$  entries

---

<sup>2</sup>30fps,  $640 \times 480$  pixels with 24-bit colour information

Because of the size of these tables

- No physical agent will have the space to store the table
- The designer would not have time to create the table
- No agent could learn all the right table entries from experience
- The designer has no guidance about how to fill the table entries in

## Example

Despite all this, TABLE-DRIVEN-AGENT does do what we want

- It implements the desired agent function

A key challenge

- Find how to write programs that produce rational behaviour
- From a smallish program
- To the extent possible

(Rather than from a vast table)

Examples show that this can be done successfully in many areas

## Example

Tables of square roots used by engineers and school children prior to the 70s

- Now replaced by a five-line program on PCs

**Simple reflex agent:** The simplest kind of agent

- These agents select actions on the basis of the current percept
- Ignore the rest of the percept history

# Simple reflex agents (cont.)

## Example

The vacuum agent is a simple reflex agent

| Percept sequence                          | Action       |
|---|--------------|
| <i>[A, Clean]</i>                         | <i>Right</i> |
| <i>[A, Dirty]</i>                         | <i>Suck</i>  |
| <i>[B, Clean]</i>                         | <i>Left</i>  |
| <i>[B, Dirty]</i>                         | <i>Suck</i>  |
| <i>[A, Clean], [A, Clean]</i>             | <i>Right</i> |
| <i>[A, Clean], [A, Dirty]</i>             | <i>Suck</i>  |
| <i>⋮</i>                                  | <i>⋮</i>     |
| <i>[A, Clean], [A, Clean], [A, Clean]</i> | <i>Right</i> |
| <i>[A, Clean], [A, Clean], [A, Dirty]</i> | <i>Suck</i>  |
| <i>⋮</i>                                  | <i>⋮</i>     |

**function** REFLEX-VACUUM-AGENT(*[location,status]*) **returns** an action

```
if status = Dirty then return Suck  
else if location = A then return Right  
else if location = B then return Left
```

Decision on current location and on whether that location contains dirt

The agent program is small compared to the corresponding table

- The largest reduction comes from ignoring the percept history
- (cuts down the number of possibilities from  $4^T$  to 4)
- When current square is dirty, action does not depend on location item (another, smaller, reduction)

# Simple reflex agents (cont.)

Simple reflex behaviours occur even in more complex environments

## Example

It is easy to imagine yourself as the driver of the automated taxi

- If the car in front brakes and its brake lights come on
- ↪ Then, you should notice this and initiate braking

Processing is done on visual input to establish the condition

- ‘The car in front is braking’

This triggers established connection in the program to action

- ↪ ‘Initiate braking’

We call such a connection a **condition-action rule**

**if** car-in-front-braking **then** initiate-braking

The simple reflex agent acts according to the rule

- The rule condition matches the current state
- Current state is as defined by the percept

## Code

**function** SIMPLE-REFLEX-AGENT(*percept*) **returns** an action  
**persistent:** *rules*, a set of condition–action rules

*state* ← INTERPRET-INPUT(*percept*)

*rule* ← RULE-MATCH(*state*, *rules*)

*action* ← *rule*.ACTION

**return** *action*

The **INTERPRET-INPUT** function

- Generates an abstracted description of current state from percept

The **RULE-MATCH** function

- Returns the first rule among those that matches the state description

Simple reflex agents have the admirable property of being simple

- But, they are also of limited intelligence

## Remark

Situations in which the simple reflex agent works

If the correct decision can be made on the basis of only the current percept

- Only if the environment is fully observable

Even a tiny bit of un-observability can be cause of serious troubles

## Example

- The braking rule assumes condition **car-in-front-braking** to be determined from current percept, a single frame of video

This works if the car in front has a centrally mounted brake light

- Unfortunately, older models have different configurations
- (tail lights, brake lights, and turn-signal lights)

Not always possible to tell from a single image whether the car is braking

A simple reflex agent driving behind such a car would either

- Brake continuously and unnecessarily
- Never brake at all

## Example

Issues arise with a vacuum agent

A simple reflex agent that has lost its location sensor, only a dirt sensor

Such an agent has two possible percepts: [Dirty] and [Clean]

- It can Suck in response to [Dirty]

What should it do in response to [Clean]?

- Moving Left fails (forever) if it happens to start in square A
- Moving Right fails (forever) if it happens to start in square B

For simple reflex agents that operate in partially observable environments

↪ Infinite loops are often unavoidable

Escape from infinite loops is possible, if the agent can randomise its actions

## Example

If the vacuum agent perceives [Clean]

- Flip a coin to choose between **Left** and **Right**
- The agent will reach the other square in an average of two steps

Then, if that square is dirty, the agent will clean it

- the task will be complete

Randomised simple reflex agents can outperform deterministic equivalents

Randomised behaviour can be rational in some multi-agent environments

- In single-agent environments, randomisation is usually not rational

## Remark

It is a useful trick that helps a simple reflex agent in some cases

- We can do better with sophisticated deterministic agents
- (in most situations)

The most effective way to handle partial observability

↪ Keep track of the part of the world that can NOT be seen now

The agent should maintain some sort of **internal state**

- The internal state must depend on the percept history
- It reflects at least some of the unobserved aspects of current state

# Model-based reflex agents (cont.)

Agents and environment

The internal state information must be updated as time goes by

It requires two kinds of knowledge to be encoded

- We need info about how the world evolves independently of the agent<sup>3</sup>
- We need info about how the agent's own actions affect the world<sup>4</sup>

Knowledge about 'how the world works' is a **model** of the world

- Can be implemented as Boolean circuits
- Principled theories
- ...

An agent that uses such a model is a **model-based agent**

---

<sup>3</sup>For example, an overtaking car generally will be closer than it was before

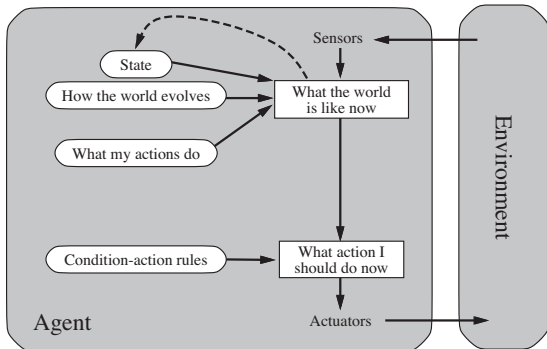

<sup>4</sup>For example, when the agent steers clockwise the car turns to the right, or after driving for five minutes northbound one is about five miles norther

# Model-based reflex agents (cont.)

The structure of the model-based reflex agent with internal state

- It shows how current percept is combined with old internal state

↪ To generate the updated description of the current state

- Based on the agent's model of how the world works

A model-based reflex agent keeps track of the current state of the world

- It uses an internal model, then it chooses an action
- The choice is done in the same way as the reflex agent

## Code

**function** MODEL-BASED-REFLEX-AGENT(*percept*) **returns** an action

**persistent:** *state*, the agent's current conception of the world state

*model*, a description of how the next state depends on current state and action

*rules*, a set of condition–action rules

*action*, the most recent action, initially none

*state* ← UPDATE-STATE(*state*, *action*, *percept*, *model*)

*rule* ← RULE-MATCH(*state*, *rules*)

*action* ← *rule*.ACTION

**return** *action*

Interesting part of agent program: Function **UPDATE-STATE**

- It is responsible for creating the new internal state description

The internal ‘state’ maintained by a model-based agent

- Not a ‘what the world is like now’ description

## Example

A taxi driving back home may have a rule telling it to fill-up with gas

- Unless it has at least 50% tank

‘Driving back home’ may seem to be an aspect of the world state

- It is actually an aspect of the agent’s internal state

The taxi could be in exactly the same place at the same time

- But towards a different destination

## Decision making of this kind differs from condition-action rules

- It involves consideration of the future
- ('What will happen if I do such-and-such?')
- ('Will that make me happy?')

In reflex agent designs this explicit information is not represented

- Its built-in rules map directly from percepts to actions
- The reflex agent brakes when it sees brake lights

## Example

A goal-based agent, in principle, could reason

If the car in front has its brake lights on, it will slow down

- The action that achieves the goal of not hitting other cars is to brake

# Goal-based agents (cont.)

## Happy hackin

The goal-based agent appears less efficient, but it is more flexible

- The knowledge that supports decisions is represented explicitly
- It can be modified

## Example

It starts to rain

The agent can update its knowledge of how effectively its brakes will operate

This automatically causes all relevant behaviours to be altered

- To suit the new conditions

For the reflex agent, we must rewrite many condition-action rules

Goals alone are not enough to generate high-quality behaviour

## Example

Many action sequences will get the taxi to destination (the goal)

- Some are quicker, safer, more reliable, or cheaper than others

Goals provide a binary distinction between ‘happy/unhappy’ states

A more general performance measure should allow a comparison of states

- How happy they would make the agent

‘Happy’ does not sound very scientific, we use the term **utility** instead

Performance measures assign a score to any sequence of environment states

- It can easily distinguish between more and less desirable ones
- (ways of getting to the taxi's destination)

## Definition

A *utility function* is kind of an internalisation of the performance

- *If internal utility function and external performance measure are in agreement, then an agent that chooses actions to maximise its utility will be rational, according to performance*

# Utility-based agents (cont.)

This is not the only way to be rational

- The rational agent program for the vacuum world
- (It has no idea what its utility function is)

Like goal-based agents, a utility-based agent has many advantages

- Flexibility and learning

A utility-based agent can make rational decisions when goals are inadequate

- When there are conflicting goals, only some of which can be achieved (for example, speed and safety), the utility function specifies the appropriate tradeoff
- When there are several goals, none of which can be achieved with certainty, utility provides a way in which the likelihood of success can be weighed against the importance of the goals

## Remark

The 'global' definition of rationality has been modified

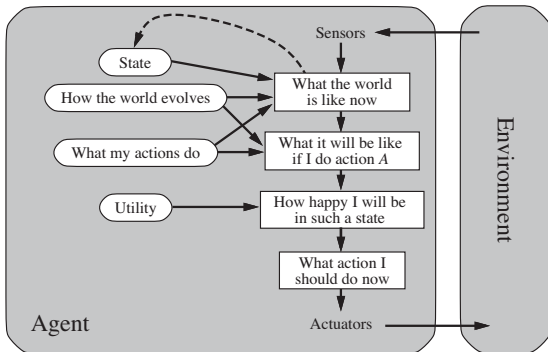

- It become a 'local' constraint on rational-agent designs

# Goal-based agents (cont.)

Model-based and utility-based agent use a model and an utility function

The utility function measures preferences among states of the world

↪ Then they choose the action leading to best expected utility

Expected utility is computed by averaging over all possible outcome states

- Weighted by the probability of the outcome

# Utility-based agents (cont.)

Is it that simple? We build agents that maximise expected utility?

It's true that such agents would be intelligent, but it's not simple

A utility-based agent has to model and keep track of environment

- These tasks have involved research
- Perception, representation, reasoning, and learning

Choosing the utility-maximising course of action is also difficult

- It requires ingenious algorithms
- Perfect rationality may still be unachievable
- (computational complexity)

We described agent programs with various methods for selecting actions

- We do not know yet how they come into being

In one of his famous early papers, Turing (1950) considers the idea of actually programming his intelligent machines by hand

- He estimates how much work this might take
- He concludes '*Some more expeditious method seems desirable*'

He proposed to build learning machines and then to teach them

## Remark

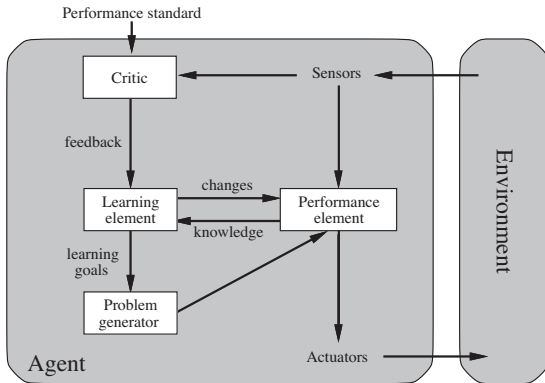

This today is the preferred method for creating state-of-the-art systems

Learning allows the agent to operate in initially unknown environments

- Improve competence beyond the initial knowledge alone

# Learning agents (cont.)

A **learning agent** can be divided into four conceptual components

- **Learning element**, responsible for making improvements
- **Performance element**, responsible for selecting external actions

# Learning agents (cont.)

The performance element is what we considered to be the agent

- It takes in percepts and decides on actions

The learning element uses feedback from the **critic** element on how it is doing and determines how the performance element should be modified

Happy hackin

The design of learning agents depends on the design of performance elements

Consider the design of an agent that learns a certain capability

- The first question is NOT ‘How am I going to get it to learn this?’  
↪ ‘What kind of performance element will my agent need to do this, once it has learned how?’

Given an agent design, learning mechanisms can be constructed

- We can improve every part of the agent

Happy hackin

## Example

The taxi makes a quick left turn across three lanes of traffic

- The critic observes the language used by other drivers

From this experience, the learning element is able to formulate a rule

↪ This was a bad action

The performance element is modified, by installation of the new rule

The generator may identify areas for improvement, suggest experiments

- Such as trying out the brakes on different road surfaces and conditions

These forms of learning need no access to external performance standards

- The standard way: Make predictions that agree with experiment

The situation is more complex for a utility-based agent

- As they wish to learn an utility information

## Example

The taxi-driving agent gets no tips from passengers who been shaken up

- The external performance standard must inform the agent that the loss of tips is a negative contribution to its overall performance
  - The agent might be able to learn
- ↪ Violent manoeuvres do not contribute to its own utility

**Learning agents**  
Agent components

Happy hackin

In summary, agents have a variety of components

- Components can be represented in many ways in the agent program

There appears to be variety among learning methods

- There is a single unifying theme

Learning is the process of modification of each component of the agent

- Bring components into agreement with feedback information
- ↪ Thereby improving the overall performance of the agent

We have been describing agent programs (in high-level terms)

Various components, whose function is to answer questions

- ‘What is the world like now?’
- ‘What action should I do now?’
- ‘What do my actions do?’

The next question is, ‘How do these components work?’

- How the components can represent the environment of the agent
