### Pattern recognition and machine learning (cont.)

Learning regularities in data and searching for patterns is a central problem

• Machine intelligence has a long and somehow successful history

The first generation of machine learning is the good old artificial intelligence

- Expert systems using knowledge extracted from humans (rules)
- Combinatorial explosion (lots of rules and exceptions to rules)
- 70's and 80's

#### Advanced topics in AI-I (CK0146) Pattern recognition (TIP8311)

### Pattern recognition and machine learning (cont.)

The second generation is basically neural networks/support vector machines

- Black-box statistical models focused on learning from data
- Prior knowledge is rather general assumptions (continuity)
- Hard to incorporate specific (complex) domain knowledge
- 80's and 90's

The third generation is integration of domain knowledge-statistical learning

- Probabilistic modelling and Bayesian framework
- Probabilistic graphical models and inference
- 00's

This course is located right in the middle of the third generation of PRML

### Terminology (cont.)

The sets  $\{x_i\}$  and  $\{t_i\}$  together are the training set, used to tune a model

• Tuning a model means determining optimal values for its parameters

The result of running a machine learning model is expressed as a function y(x)

- it takes a new input vector x (say, a new image), it processes it
- ullet it generates an output vector  $oldsymbol{y}$ , encoded as the target vector

The precise form of y(x) is determined during the learning or training phase

Once the model is trained, it can determine the identity of new input vectors

the test set

The ability to categorise correctly test examples is known as generalisation

Polynomial curve fitting

We consider a simple regression problem to motive a number of key concepts

Suppose we observe a real-valued input variable x, and we wish to use this observation to predict the value of a real-valued target variable t

• The data for this example is generated from the function  $\sin(2\pi x)$  with *random noise* included in the target values

Now suppose that we are given a training set comprising

- N observations of x,  $x \equiv (x_1, \dots, x_N)^T$
- N observations of t,  $t \equiv (t_1, \ldots, t_N)^T$

UFC/DC ATAI-I / PR 2016.2

erminolog

An example

### Polynomial curve fitting (cont.)

Training data of N = 10 points, blue circles

 each comprising an observation of the input variable x along with the corresponding target variable t

The unknown function  $\sin(2\pi x)$  is used to generate the data, green curve

- Goal: Predict the value of t for some new value of x
- without knowledge of the green curve

The input training data x was generated by choosing values of  $x_n$ , for n = 1, ..., N, that are spaced uniformly in the range [0, 1]

The target training data t was obtained by computing values  $\sin(2\pi x_n)$  of the function and adding a small level of Gaussian noise

PRML

This cours

Terminolog

An example

### Polynomial curve fitting (cont.)

For the moment, however, we shall proceed informally

We consider a simple approach based on curve fitting

• We shall fit the data using a polynomial function of the form

$$y(x, \mathbf{w}) = w_0 + w_1 x + w_2 x^2 + \dots + w_M x^M = \sum_{j=0}^{M} w_j x^j$$
 (1)

- M is the order of the polynomial,  $x^j$  denotes x raised to the power of j
- The polynomial coefficients  $w_0, \ldots, w_M$  are collected in the vector **w**

The polynomial function  $y(x, \mathbf{w})$ 

- Nonlinear function of the inputs x
- Linear function
   of the coefficients w

Functions that are linear in the unknown parameters are called linear models

Advanced topics in AI-I (CK0146) Pattern recognition (TIP8311)

PRML

\_ . . .

An example

### Polynomial curve fitting (cont.)

Goal: Exploit the training set to make predictions of the value t of the target variable, for some new value x of the input variable

• Implicitly, try to discover the underlying function  $\sin(2\pi x)$ 

This is intrinsically a difficult problem:

- We have to generalise from a finite data set
- The observed data are corrupted with noise

For a given x there is uncertainty as to the appropriate value for t

- Probability theory provides a framework for expressing such uncertainty in a precise and quantitative manner
- Decision theory allows us to exploit this probabilistic representation in order to make predictions that are optimal, according to an appropriate criteria

#### Advanced topics in AI-I (CK0146) Pattern recognition (TIP8311)

UFC/DC ATAI-I / PR 2016.2

PRML

Ferminology

An example

### Polynomial curve fitting (cont.)

The coefficients values are obtained by fitting the polynomial to training data

- By minimising an error function, a measure of misfit between function  $y(x, \mathbf{w})$ , for any given value of  $\mathbf{w}$ , and the training set data points
- A choice of error function is the sum of the squares of the errors between predictions  $y(x_n, \mathbf{w})$  for each point  $x_n$  and corresponding target values  $t_n$

$$E(\mathbf{w}) = \frac{1}{2} \sum_{n=1}^{N} \left( y(x_n, \mathbf{w}) - t_n \right)^2$$
 (2)

 It is a nonnegative quantity that would be zero if and only if function y(x, w) were to pass through each training data point

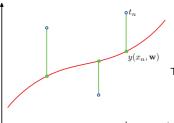

UFC/DC ATAI-I / PR 2016.2

PRML

An example

### Polynomial curve fitting (cont.)

Error function  $E(\mathbf{w})$  corresponds to (one half of) the sum of the squares of the displacements (vertical green bars) of each data point  $t_n$  from function  $y(x, \mathbf{w})$ 

$$E(\mathbf{w}) = \frac{1}{2} \sum_{n=1}^{N} \left( y(x_n, \mathbf{w}) - t_n \right)^2$$

To solve the curve fitting problem

- Choose the value of  $\mathbf{w}$  for which  $E(\mathbf{w})$  is as small as possible
- $(\star)$  Because the error function is a quadratic function of the coefficients w, its derivatives with respect to the coefficients will be linear in the elements of w
- The minimisation of  $E(\mathbf{w})$  has a unique solution,  $\mathbf{w}^*$ , found in closed form
- The resulting polynomial is given by the function  $y(x, \mathbf{w}^*)$

### Polynomial curve fitting (cont.)

#### **Exercis**

Consider the sum-of-squares error function given in Equation 2,

$$E(\mathbf{w}) = \frac{1}{2} \sum_{n=1}^{N} \left( y(\mathbf{x}_n, \mathbf{w}) - t_n \right)^2,$$

in which the function  $y(x, \mathbf{w})$  is given by the polynomial in Equation 1

$$y(x, \mathbf{w}) = w_0 + w_1 x + w_2 x^2 + \dots + w_M x^M = \sum_{j=0}^{M} w_j x^j$$

Show that the coefficients  $\mathbf{w} = w_i$  that minimize this error function are given by the solution to the following set of linear equations

$$\sum_{i=0}^{M} A_{ij} w_j = T_i$$

Substituting Eq. 1 into Eq. 2 and then differentiating wrt  $w_i$ , we get

$$\sum_{n=1}^{N} \left( \sum_{j=0}^{M} w_j x_n^i - t_n \right) x_n^i = 0$$

Rearranging terms gives us the required results

RMI

. .

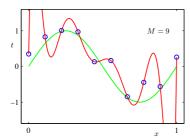

Torminolom.

An example

### Polynomial curve fitting (cont.)

A higher order polynomial (M = 9) gives an excellent fit to the training data

• The polynomial passes exactly through each data point and  $E(\mathbf{w}^*) = 0$ 

However, the fitted curve oscillates wildly and gives a very poor representation of the function  $\sin(2\pi x)$ , this is a behaviour that is known as **over-fitting** 

#### Advanced topics in AI-I (CK0146) Pattern recognition (TIP8311)

UFC/DC ATAI-I / PR 2016.2

PRML

This course

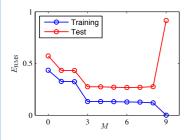

Terminolog

An example

### Polynomial curve fitting (cont.)

Graphs of the training and test set RMS errors for various values of M

 The test error is a a measure of how well we are doing in predicting the values of t for new data observations of x

- Small values of M (0, 1 and 2) give relatively large values of test set error
- Values of M in the range  $3 \le M \le 8$  give small values for the test set error

Low-order polynomials are rather inflexible and are incapable of capturing the oscillations in the function  $\sin(2\pi x)$ , whereas high-order polynomials are too flexible and capable of capturing also the oscillations in the additive noise

#### Advanced topics in AI-I (CK0146) Pattern recognition (TIP8311)

UFC/DC ATAI-I / PR 2016.2

PRML

Terminology

An example

### Polynomial curve fitting (cont.)

How to get good generalisation by making accurate predictions for new data?

We can obtain some quantitative insight into the dependence of the generalisation performance on M by considering a separate test set

• 100 new points generated using the same procedure used to generate the training set points, but with new choices for the random noise values

For each choice of M, we evaluate the residual value of  $E(\mathbf{w}^*)$  for the training data, and we also evaluate the residual value of  $E(\mathbf{w}^*)$  for the test data set

It is sometimes more convenient to use the root-mean-square (RMS) error

$$E_{RMS} = \sqrt{2E(\mathbf{w}^*)/N} \tag{3}$$

The division by N allows a consistent comparison of datasets of different sizes and square root ensures that  $E_{RMS}$  is measured on the same scale/units as t

#### Advanced topics in AI-I (CK0146) Pattern recognition (TIP8311)

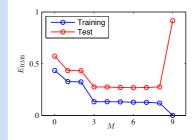

UFC/DC ATAI-I / PR 2016.2

PRML
This course

An example

### Polynomial curve fitting (cont.)

For M = 9, the training set error goes to zero (intuitively, as this polynomial contains 10 degrees of freedom corresponding to the 10 coeffs  $w_0, \ldots, w_9$ )

- It can be tuned exactly to the 10 data points in the training set
- The test set error has become large
- The corresponding function  $y(x, \mathbf{w}^*)$  exhibits wild oscillations

#### Remark

Paradoxical: A polynomial of given order contains all lower order polynomials

ullet The M=9 polynomial is at least as good as the M=3 polynomial

Supposing that the best predictor would be the generating function  $\sin(2\pi x)$ 

- A power series expansion of  $\sin(2\pi x)$  contains terms of all orders
- $\bullet$  The results should improve monotonically as we increase M

### Polynomial curve fitting (cont.)

We can gain some insight into the problem by examining the values of the coefficients  $\mathbf{w}^*$  that are obtained by fitting polynomials of various order

ullet As M increases, the magnitude of the coefficients typically gets larger For the M=9 polynomial, the coefficients became finely tuned to the data

|               | M=0  | M = 1 | M = 6  | M = 9       |
|---------------|------|-------|--------|-------------|
| $w_0^{\star}$ | 0.19 | 0.82  | 0.31   | 0.35        |
| $w_1^{\star}$ |      | -1.27 | 7.99   | 232.37      |
| $w_2^{\star}$ |      |       | -25.43 | -5321.83    |
| $w_3^*$       |      |       | 17.37  | 48568.31    |
| $w_4^{\star}$ |      |       |        | -231639.30  |
| $w_5^{\star}$ |      |       |        | 640042.26   |
| $w_6^{\star}$ |      |       |        | -1061800.52 |
| $w_7^{\star}$ |      |       |        | 1042400.18  |
| $w_8^{\star}$ |      |       |        | -557682.99  |
| $w_9^{\star}$ |      |       |        | 125201.43   |
|               |      |       |        |             |

- Large positive/negative values, so the polynomial matches each of the data points exactly
- Between points the function exhibits the large oscillations

Intuitively, what is happening is that the more flexible polynomials with larger values of M are becoming increasingly tuned to the random noise on the target

### Polynomial curve fitting (cont.)

Number of parameters is not necessarily the best measure of model complexity

- Why limit the number of parameters in a model according to the size of the available training set?
- It would seem more reasonable to choose model complexity according to the problem complexity

We shall see that the least squares approach to finding the model parameters represents a specific case of maximum likelihood, and that the over-fitting problem can be understood as a general property of maximum likelihood

 By adopting a Bayesian approach, the over-fitting problem can be avoided

We will see that there is no difficulty from a Bayesian perspective in employing models for which the number of parameters greatly exceeds the data size

 In a Bayesian model, the effective number of parameters adapts automatically to the size of the data set

UFC/DC ATAI-I / PR 2016.2

PRML

Terminology
An example

nology

### Polynomial curve fitting (cont.)

We continue with the current approach and consider how we can apply it to data sets of limited size where we may wish to use relatively complex models

One technique that is often used to control over-fitting is regularisation

- It involves adding a penalty term to the error function  $E(\mathbf{w})$ , in order to discourage the coefficients from reaching large values
- The simplest such penalty term takes the form of a sum of squares of all of the coefficients, leading to a modified error function of the form

$$\tilde{E}(\mathbf{w}) = \frac{1}{2} \sum_{n=1}^{N} (y(x_n, \mathbf{w}) - t_n)^2 + \frac{\lambda}{2} ||\mathbf{w}||^2$$
 (4)

- where  $||\mathbf{w}||^2 = \mathbf{w}^T \mathbf{w} = w_0^2 + w_1^2 + \cdots + w_M^2$
- ullet Coefficient  $\lambda$  governs the relative importance of the regularisation term, compared with the standard sum-of-squares error term

Again, the error function above can be minimised exactly in closed form (\*)

UFC/DC ATAI-I / PR 2016.2

An example

### Polynomial curve fitting (cont.)

Write down the set of coupled linear equations, analogous to

$$\sum_{j=0}^{M} A_{ij} w_j = T_i$$

satisfied by the coefficients  $w_i$  which minimise the regularised sum-of-squares error function given by Equation 4

$$\tilde{E}(\mathbf{w}) = \frac{1}{2} \sum_{n=1}^{N} (y(x_n, \mathbf{w}) - t_n)^2 + \frac{\lambda}{2} ||\mathbf{w}||^2$$

For the regularised sum-of-squares error function given by Equation 4, the corresponding linear equations are again obtained by differentiation

• They take the same form as Equation 26, but with  $A_{ii}$  replaced by  $\tilde{A}_{ii}$ 

$$\tilde{A}_{ij} = A_{ij} + \lambda I_{ij}$$

# Polynomial curve fitting (cont.)

The impact of the regularisation term on the generalisation error can be seen by plotting the RMS error (Equation 3) for both training and test sets, v ln  $\lambda$ 

 $\lambda$  controls the effective model complexity and sets the degree of over-fitting

### Polynomial curve fitting (cont.)

By minimising an error function, we must determine a suitable value of model complexity, whether the polynomial order M or the regularisation coefficient  $\lambda$ 

A way of achieving this is to take available data and then partition it into

- A training set, to determine w for different settings of model complexity
- A separate validation set, to find an optimal value of model complexity Seeing the inherent data scarcity, this is too wasteful of valuable training data

One solution to this is to use a technique commonly known as cross-validation

### Polynomial curve fitting (cont.)

S-fold cross-validation allows a proportion (S-1)/S of the available data to be used for training while making use of all of the data to asses performance

This procedure is repeated for all S possible choices for the held-out group, the red blocks, and performance scores from the S runs are averaged

When data is particularly scarce, it is appropriate to consider the case S = N, where N is the total number of data points, leave-one-out cross-validation
