Terminology

An example

Pattern recognition and machine learning

Pattern recognition is concerned w automatic discovery of *regularities* in data through computer algorithms and the use of such regularities to take actions

- Example
 - Typical example is the classification of the data into different categories

A machine capable of recognising handwritten digits from images (28×28 pixels) represented as input vectors (**x**, comprising $28 \times 28 = 784$ numbers)

- Produce the identity of the digit (0,...,9)
- Not a trivial task (variety of handwriting)

Pattern recognition and machine learning (cont.)

Learning regularities in data and searching for patterns is a central problem

• Machine intelligence has a long and somehow successful history

The first generation of machine learning is the good old artificial intelligence

- Expert systems using knowledge extracted from humans (rules)
- Combinatorial explosion (lots of rules and exceptions to rules)
- 70's and 80's

UFC/DC ATAI-I / PR 2017.1

PRML

This course

- Terminology
- An example

Pattern recognition and machine learning (cont.)

The second generation is basically neural networks/support vector machines

- Black-box statistical models focused on learning from data
- Prior knowledge is rather general assumptions (continuity)
- Hard to incorporate specific (complex) domain knowledge
- 80's and 90's

The third generation is integration of domain knowledge-statistical learning

- Probabilistic modelling and Bayesian framework
- Probabilistic graphical models and inference
- 00's

This course is located right in the middle of the third generation of PRML

Terminology (cont.)

The sets {x_i} and {t_i} together are the training set, used to tune a model
Tuning a model means determining optimal values for its parameters

The result of running a machine learning model is expressed as a function y(x)

- it takes a new input vector x (say, a new image), it processes it
- it generates an output vector y, encoded as the target vector

The precise form of $\mathbf{y}(\mathbf{x})$ is determined during the learning or training phase

Once the model is trained, it can determine the identity of new input vectors

• the test set

The ability to categorise correctly test examples is known as generalisation

Polynomial curve fitting

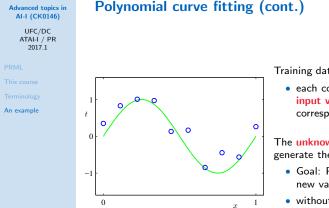

We consider a simple regression problem to motive a number of key concepts

Suppose we observe a real-valued input variable x, and we wish to use this observation to predict the value of a real-valued target variable t

 The data for this example is generated from the function sin(2πx) with random noise included in the target values

Now suppose that we are given a training set comprising

- N observations of x, $\mathbf{x} \equiv (x_1, \dots, x_N)^T$
- N observations of t, $t \equiv (t_1, \ldots, t_N)^T$

Training data of N = 10 points, blue circles

 each comprising an observation of the input variable x along with the corresponding target variable t

The unknown function $sin(2\pi x)$ is used to generate the data, green curve

- Goal: Predict the value of t for some new value of x
- without knowledge of the green curve

The input training data x was generated by choosing values of x_n , for n = 1, ..., N, that are spaced uniformly in the range [0, 1]

The target training data t was obtained by computing values $sin(2\pi x_n)$ of the function and adding a small level of Gaussian noise

UFC/DC ATAI-I / PR 2017.1

PRML

This course

Terminology

An example

Polynomial curve fitting (cont.)

Goal: Exploit the training set to make predictions of the value t of the target variable, for some new value x of the input variable

• Implicitly, try to discover the underlying function $sin(2\pi x)$

This is intrinsically a difficult problem:

- We have to generalise from a finite data set
- The observed data are corrupted with noise

For a given x there is uncertainty as to the appropriate value for t

- Probability theory provides a framework for expressing such uncertainty in a precise and quantitative manner
- Decision theory allows us to exploit this probabilistic representation in order to make predictions that are optimal, according to an appropriate criteria

UFC/DC ATAI-I / PR 2017.1

PRML

This course

Terminology

An example

Polynomial curve fitting (cont.)

For the moment, however, we shall proceed informally We consider a simple approach based on curve fitting

• We shall fit the data using a polynomial function of the form

$$y(x, \mathbf{w}) = w_0 + w_1 x + w_2 x^2 + \dots + w_M x^M = \sum_{j=0}^M w_j x^j$$
 (1)

- *M* is the order of the polynomial, x^j denotes x raised to the power of j
- The polynomial coefficients w_0, \ldots, w_M are collected in the vector ${f w}$
- The polynomial function $y(x, \mathbf{w})$

- Nonlinear function of the inputs *x*
- Linear function of the coefficients w

Functions that are linear in the unknown parameters are called linear models

> UFC/DC ATAI-I / PR 2017.1

PRML

This cours

Terminology

An example

Polynomial curve fitting (cont.)

The coefficients values are obtained by fitting the polynomial to training data

- By minimising an error function, a measure of misfit between function $y(x, \mathbf{w})$, for any given value of \mathbf{w} , and the training set data points
- A choice of error function is the sum of the squares of the errors between predictions y(xn, w) for each point xn and corresponding target values tn

$$E(\mathbf{w}) = \frac{1}{2} \sum_{n=1}^{N} \left(y(x_n, \mathbf{w}) - t_n \right)^2$$
(2)

 It is a nonnegative quantity that would be zero if and only if function y(x, w) were to pass through each training data point

UFC/DC ATAI-I / PR 2017.1

PRMI

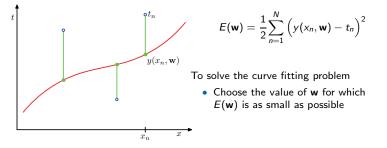

This course

Terminology

An example

Polynomial curve fitting (cont.)

Error function $E(\mathbf{w})$ corresponds to (one half of) the sum of the squares of the displacements (vertical green bars) of each data point t_n from function $y(x, \mathbf{w})$

 (\star) Because the error function is a quadratic function of the coefficients w, its derivatives with respect to the coefficients will be linear in the elements of w

- The minimisation of $E(\mathbf{w})$ has a unique solution, \mathbf{w}^* , found in closed form
- The resulting polynomial is given by the function $y(x, \mathbf{w}^*)$

UFC/DC ATAI-I / PR 2017.1

PRMI

This course

Terminology

An example

Polynomial curve fitting (cont.)

Exercise

Consider the sum-of-squares error function given in Equation 2,

$$E(\mathbf{w}) = \frac{1}{2} \sum_{n=1}^{N} \left(y(x_n, \mathbf{w}) - t_n \right)^2,$$

in which the function $y(x, \mathbf{w})$ is given by the polynomial in Equation 1

$$y(x, \mathbf{w}) = w_0 + w_1 x + w_2 x^2 + \dots + w_M x^M = \sum_{j=0}^M w_j x^j$$

Show that the coefficients $\mathbf{w} = w_i$ that minimize this error function are given by the solution to the following set of linear equations

$$\sum_{j=0}^{M} A_{ij} w_j = T_i$$

Substituting Eq. 1 into Eq. 2 and then differentiating wrt w_i , we get

$$\sum_{n=1}^{N} \Big(\sum_{j=0}^{M} w_j x_n^i - t_n\Big) x_n^i = 0$$

Rearranging terms gives us the required results

Polynomial curve fitting (cont.)

There still remains the problem of choosing the order \boldsymbol{M} of the polynomial

• model comparison or model selection

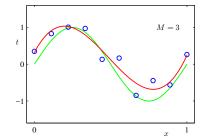

Examples of the results of fitting polynomials of different order to the data

The constant (M = 0) and first order (M = 1) polynomials give poor fits to data, and consequently a rather poor representation of the function $sin(2\pi x)$

Polynomial curve fitting (cont.)

The third order (M = 3) polynomial gives a good fit to the function $sin(2\pi x)$

UFC/DC ATAI-I / PR 2017.1

PRML

This course

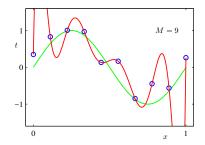

Terminology

An example

Polynomial curve fitting (cont.)

A higher order polynomial (M = 9) gives an excellent fit to the training data

• The polynomial passes exactly through each data point and $E(\mathbf{w}^{\star}) = 0$

However, the fitted curve oscillates wildly and gives a very poor representation of the function $sin(2\pi x)$, this is a behaviour that is known as **over-fitting**

> UFC/DC ATAI-I / PR 2017.1

PRML

This course

Terminology

An example

Polynomial curve fitting (cont.)

How to get good generalisation by making accurate predictions for new data?

We can obtain some quantitative insight into the dependence of the generalisation performance on M by considering a separate test set

 100 new points generated using the same procedure used to generate the training set points, but with new choices for the random noise values

For each choice of M, we evaluate the residual value of $E(\mathbf{w}^*)$ for the training data, and we also evaluate the residual value of $E(\mathbf{w}^*)$ for the test data set

It is sometimes more convenient to use the root-mean-square (RMS) error

$$E_{RMS} = \sqrt{2E(\mathbf{w}^{\star})/N} \tag{3}$$

The division by N allows a consistent comparison of datasets of different sizes and square root ensures that E_{RMS} is measured on the same scale/units as t

UFC/DC ATAI-I / PR 2017.1

PRML

This course

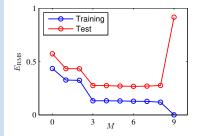

Terminology

An example

Polynomial curve fitting (cont.)

Graphs of the training and test set RMS errors for various values of M

 The test error is a a measure of how well we are doing in predicting the values of t for new data observations of x

- Small values of *M* (0, 1 and 2) give relatively large values of test set error
- Values of *M* in the range 3 ≤ *M* ≤ 8 give small values for the test set error

Low-order polynomials are rather inflexible and are incapable of capturing the oscillations in the function $\sin(2\pi x)$, whereas high-order polynomials are too flexible and capable of capturing also the oscillations in the additive noise

UFC/DC ATAI-I / PR 2017.1

PRMI

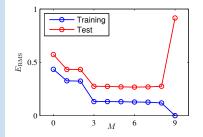

This cours

Terminology

An example

Polynomial curve fitting (cont.)

For M = 9, the training set error goes to zero (intuitively, as this polynomial contains 10 degrees of freedom corresponding to the 10 coeffs w_0, \ldots, w_9)

- It can be tuned exactly to the 10 data points in the training set
- The test set error has become large
- The corresponding function $y(x, \mathbf{w}^*)$ exhibits wild oscillations

Remark

Paradoxical: A polynomial of given order contains all lower order polynomials

• The M = 9 polynomial is at least as good as the M = 3 polynomial

Supposing that the best predictor would be the generating function $sin(2\pi x)$

- A power series expansion of $sin(2\pi x)$ contains terms of all orders
- The results should improve monotonically as we increase M

UFC/DC ATAI-I / PR 2017.1

PRML

This course

Terminology

An example

Polynomial curve fitting (cont.)

We can gain some insight into the problem by examining the values of the coefficients w^* that are obtained by fitting polynomials of various order

• As *M* increases, the magnitude of the coefficients typically gets larger For the M = 9 polynomial, the coefficients became finely tuned to the data

	M = 0	M = 1	M = 6	M = 9	
w_0^{\star}	0.19	0.82	0.31	0.35	 Large positive/negative
$w_0^{\star} \ w_1^{\star} \ w_2^{\star} \ w_3^{\star} \ w_4^{\star} \ w_5^{\star}$		-1.27	7.99	232.37	values, so the polynomial
w_2^{\star}			-25.43	-5321.83	matches each of the data
w_3^{\star}			17.37	48568.31	
w_4^{\star}				-231639.30	points exactly
w_5^{\star}				640042.26	 Between points the function
w_{6}^{\star} w_{7}^{\star}				-1061800.52	exhibits the large oscillations
w_7^{\star}				1042400.18	exhibits the large oscillations
w_{8}^{\star} w_{9}^{\star}				-557682.99	
w_9^{\star}				125201.43	

Intuitively, what is happening is that the more flexible polynomials with larger values of M are becoming increasingly tuned to the random noise on the target

UFC/DC ATAI-I / PR 2017.1

PRML

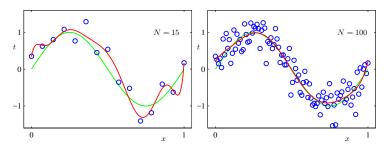

This cours

Terminology

An example

Polynomial curve fitting (cont.)

The behaviour of a model of given complexity (M = 9) as data size is varied

Over-fitting problem become less severe as the data size increases

- The larger the data set, the more complex (more flexible) the model that we can afford to fit to the data
- One heuristic is 'the number of data points should be no less than some multiple (5 or 10) of the number of adaptive parameters in the model'

UFC/DC ATAI-I / PR 2017.1

PRML

This course

Terminology

An example

Polynomial curve fitting (cont.)

Number of parameters is not necessarily the best measure of model complexity

- Why limit the number of parameters in a model according to the size of the available training set?
- It would seem more reasonable to choose model complexity according to the problem complexity

We shall see that the least squares approach to finding the model parameters represents a specific case of maximum likelihood, and that the over-fitting problem can be understood as a general property of maximum likelihood

• By adopting a **Bayesian approach**, the over-fitting problem can be avoided

We will see that there is no difficulty from a Bayesian perspective in employing models for which the number of parameters greatly exceeds the data size

• In a Bayesian model, the effective number of parameters adapts automatically to the size of the data set

> UFC/DC ATAI-I / PR 2017.1

PRML

This course

Terminology

An example

Polynomial curve fitting (cont.)

We continue with the current approach and consider how we can apply it to data sets of limited size where we may wish to use relatively complex models

One technique that is often used to control over-fitting is regularisation

- It involves adding a penalty term to the error function E(w), in order to discourage the coefficients from reaching large values
- The simplest such penalty term takes the form of a sum of squares of all of the coefficients, leading to a modified error function of the form

$$\tilde{E}(\mathbf{w}) = \frac{1}{2} \sum_{n=1}^{N} (y(x_n, \mathbf{w}) - t_n)^2 + \frac{\lambda}{2} ||\mathbf{w}||^2$$
(4)

- where $||\mathbf{w}||^2 = \mathbf{w}^T \mathbf{w} = w_0^2 + w_1^2 + \dots + w_M^2$
- Coefficient λ governs the relative importance of the regularisation term, compared with the standard sum-of-squares error term

Again, the error function above can be minimised exactly in closed form (\star)

UFC/DC ATAI-I / PR 2017.1

PRML

This course

Terminology

An example

Polynomial curve fitting (cont.)

Exercise

Write down the set of coupled linear equations, analogous to

$$\sum_{j=0}^{M} A_{ij} w_j = T_i$$

satisfied by the coefficients w_i which minimise the regularised sum-of-squares error function given by Equation 4

$$ilde{E}(\mathbf{w}) = rac{1}{2} \sum_{n=1}^{N} (y(\mathsf{x}_n, \mathbf{w}) - t_n)^2 + rac{\lambda}{2} ||\mathbf{w}||^2$$

For the regularised sum-of-squares error function given by Equation 4, the corresponding linear equations are again obtained by differentiation

• They take the same form as Equation 26, but with A_{ii} replaced by \tilde{A}_{ii}

$$\tilde{A}_{ij} = A_{ij} + \lambda I_{ij}$$

UFC/DC ATAI-I / PR 2017.1

PRMI

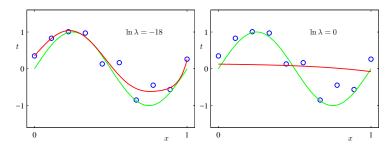

This course

Terminology

An example

Polynomial curve fitting (cont.)

Fitting the polynomial of order M = 9 to the data using a regularised error

• For $\ln \lambda = -18$ (it's a small value for λ), over-fitting is suppressed

• For $\ln \lambda = 0$ (it's a large value for λ), we obtain again a poor fit

UFC/DC ATAI-I / PR 2017.1

PRMI

This cours

Terminology

An example

Polynomial curve fitting (cont.)

Coefficients \mathbf{w}^{\star} for M = 9 polynomials with varying regularisation parameter λ

	$\ln \lambda = -\infty$	$\ln \lambda = -18$	$\ln \lambda = 0$
w_0^{\star}	0.35	0.35	0.13
w_1^{\star}	232.37	4.74	-0.05
w_2^{\star}	-5321.83	-0.77	-0.06
w_3^{\star}	48568.31	-31.97	-0.05
w_4^{\star}	-231639.30	-3.89	-0.03
w_5^{\star}	640042.26	55.28	-0.02
w_6^{\star}	-1061800.52	41.32	-0.01
w_7^{\star}	1042400.18	-45.95	-0.00
w_8^{\star}	-557682.99	-91.53	0.00
w_9^{\star}	125201.43	72.68	0.01

- $\ln \lambda = -\infty$ corresponds to an unregularised model ($\lambda = 0$)
- As λ increases, the magnitude of the coefficients gets smaller

Regularisation has the effect of reducing the magnitude of the coefficients

UFC/DC ATAI-I / PR 2017.1

PRMI

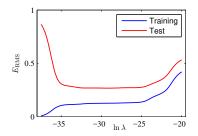

This course

Terminology

An example

Polynomial curve fitting (cont.)

The impact of the regularisation term on the generalisation error can be seen by plotting the RMS error (Equation 3) for both training and test sets, v ln λ

 λ controls the effective model complexity and sets the degree of over-fitting

> UFC/DC ATAI-I / PR 2017.1

PRML

This course

Terminology

An example

Polynomial curve fitting (cont.)

By minimising an error function, we must determine a suitable value of model complexity, whether the polynomial order M or the regularisation coefficient λ

A way of achieving this is to take available data and then partition it into

- A training set, to determine w for different settings of model complexity
- A separate validation set, to find an optimal value of model complexity
 Seeing the inherent data scarcity, this is too wasteful of valuable training data

One solution to this is to use a technique commonly known as cross-validation

UFC/DC ATAI-I / PR 2017.1

PRML

This course

Terminology

An example

Polynomial curve fitting (cont.)

S-fold cross-validation allows a proportion (S - 1)/S of the available data to be used for training while making use of all of the data to asses performance

run 1
run 2
run 3
run 4

For the S = 4 case, we take all of the available data and the we partition it into S groups

• in the simplest case these are of equal size

^{run 3} S-1 of the groups (white blocks) are used to train a set of models, the remaining group (red block) is used for evaluating their performance

This procedure is repeated for all S possible choices for the held-out group, the red blocks, and performance scores from the S runs are averaged

When data is particularly scarce, it is appropriate to consider the case S = N, where N is the total number of data points, leave-one-out cross-validation
